

First step

Create your python-based soc description, you'll need dsx and [SocLib](#) modules:

```
from dsx import *
from soclib import *
```

Always import those two modules in this order or you'll experience some strange import failures.

Task declaration

Then declare some tasks. See [DsxTaskModel](#), [DsxTasks](#), [SrlApi](#)

Tcg

Now you can create a Task and Control Graph. See [DsxTcg](#).

Posix Test

Now create a posix version of your application

```
tcg.generate(Posix())
```

Compile, test, debug

See [DsxPosix](#).

Create your SoC

See [SocCreation?](#).

Mapping

See [DsxMapping](#).

Compile the simulator, ?

```
mapper.generate( MutekS() )
```

or

```
mapper.generate( MutekH() )
```

Run, debug

You may change some flags about [MutekS](#).

You're on your own, use [CabaSimulatorFlags](#), maybe use [GtkWave?](#).
